Author information

Abstract

Background

The tripeptide glutathione (GSH) is the most abundant antioxidant found in cells and is indispensable in humans. Increasing evidence suggests that oxidative stress contributes to a variety of chronic diseases. Dietary supplementation to arrest oxidative stress is a promising approach to disease prevention. This controlled clinical research does not evaluate the efficacy of oral glutathione supplementation.

Objectives

The study objectives were to determine the effects of oral glutathione supplementation on systemic oxidative stress biomarkers in humans.

Design

This was a randomized, double-blind, placebo-controlled clinical trial.

Setting/location

The study was conducted at Bastyr University Research Institute, Kenmore, WA, and Bastyr University Research Institute, Seattle, WA.

Subjects

Forty (40) adult volunteers without serious or chronic illness participated in the study.

Intervention

Oral GSH supplementation (500 mg/day) for 30 days was the intervention.

Outcome measures

Primary outcome measures included change in serum/plasma malondialdehyde, urinary 8-hydroxy-2′-deoxyguanosine (8-OHdG), and urinary 8-iso-prostaglandin $F_{2\alpha}$. Secondary outcomes included change in erythrocyte GSH concentration, urinary 8-OHdG, and urinary 15-keto-dihydro-prostaglandin $F_{2\alpha}$ (15-keto-PGF$_{2\alpha}$). Serum/plasma and urinary measurements were taken at baseline and at 30 days.

Results

There were no differences in oxidative stress biomarkers between groups at baseline or 30 days. Twenty-nine (29) participants completed the study (14 placebo, 15 GSH). Erythrocyte GSH concentration increased in the GSH group (mean 0.16 ± 0.07 vs. 0.19 ± 0.06 mM; $p = 0.04$) but not in the placebo group (mean 0.16 ± 0.07 vs. 0.17 ± 0.05 mM; $p = 0.5$). Urinary 8-OHdG increased in the GSH group (mean 3.6 ± 2.2 vs. 4.7 ± 2.5 ng/mg creatinine; $p = 0.04$) and was unchanged in the placebo group. Urinary 15-keto-PGF$_{2\alpha}$ increased in the GSH group (mean 1.2 ± 0.5 vs. 1.5 ± 0.6 ng/mg creatinine; $p = 0.04$) and was unchanged in the placebo group.

Conclusions

No significant changes were observed in biomarkers of oxidative stress, including malondialdehyde and 8-iso-prostaglandin $F_{2\alpha}$, as a result of glutathione supplementation at healthy subjects.

Introduction

Reactive oxygen species (ROS) is a term used to describe a number of free radicals and peroxides, including superoxide, hydroxyl radical, peroxynitrite, and hydrogen peroxide. ROS are produced in cells as the detoxification of endogenous and exogenous toxins, during the inflammatory response, and during normal cellular metabolism.[1] Antioxidants are substances that protect cells from the damaging effects of oxidation. Oxidative stress is the result of an imbalance between the production of free radicals and the ability of antioxidant defenses to counteract their harmful effects.[2] Oxidative stress is thought to play a role in the development of many chronic diseases, including cancer, heart disease, autoimmune disorders, chronic fatigue syndrome, chronic viral infections, and neurodegenerative diseases such as Alzheimer's disease and Parkinson's disease.[3–5] Although the experimental research to date has demonstrated a correlation between free radical overproduction and oxidative damage to cellular components, the experimental research supports increased dietary consumption of antioxidants as a promising approach to disease prevention.[6–8]

Because of the theoretical benefits of antioxidants, dietary supplements are widely used in various acute and chronic diseases, including cancer and neurodegenerative disorders.[9] Some findings from exposure to environmental toxicants, such as pesticides, appear to increase oxidative stress and to increase the risk of developing Parkinson's disease.[10] Glutathione is the most abundant antioxidant found in cells and is indispensable to the detoxification of many xenobiotics, and it is considered the most important endogenous antioxidant produced by the gastrointestinal tract. Moreover, in tissue culture, glutathione supplementation has been demonstrated to [...] antioxidants, and glutathione is considered to be the most important of these.[11–13] Glutathione is a tripeptide composed of glutamine, cysteine, and glycine.[14] GSH is the most abundant intracellular thiol, and it is found in almost every cell in the body.[15] Glutathione is found in high concentrations in the liver, lens of the eye, lung epithelial lining fluid, and bone marrow.[16] Glutathione is found in high concentrations in the gastrointestinal tract. However, in most foods, glutathione is present in low concentrations.[17
